13. SUPPLEMENTARY NOTES

14. ABSTRACT-LIMIT 200 WORDS

The evaporation of sulfur mustard from concrete was studied as a function of temperature, drop size, and air flow rate using the same instrumentation as prior studies on glass and sand. The evaporation rate increased with higher temperature, drop size, and wind speed; an empirical equation was determined that would allow for the calculation of the evaporation rate given the atmospheric conditions. The data collected provide input for the validation of empirical and physics-based models on the evaporation of agent designed by other authors. Comparisons with the evaporation rates of sulfur mustard from glass and sand are given.

EVAPORATION RATES OF CHEMICAL WARFARE AGENTS

MEASURED USING 5 CM WIND TUNNELS

III. MUNITION-GRADE SULFUR MUSTARD ON CONCRETE

1. INTRODUCTION

The evaporation rate of the vesicant chemical warfare agent, sulfur mustard ($\{\text{bis}(2\text{-chloroethyl})\text{ sulfide}, (\text{ClCH}_2\text{CH}_2)_2\text{S}\}$, abbreviated H), from glass and three types of sand has been previously reported.^{1,2} In this work, the evaporation of 77% pure munition-grade sulfur mustard from concrete was measured.

The design of the 5 cm laboratory-sized wind tunnels³ and the wind tunnel characteristics' compared to other wind tunnel and outdoor measurements have been published.^{4,5} The vapors of sulfur mustard were collected using thermal desorption tubes and quantified using standard methodology. This report describes how the data were analyzed and demonstrates the robustness of the set of data that will be passed to the modelers for eventual incorporation into field models such as VLSTRACK. Comparisons to previous agent evaporation data are provided.

2. EXPERIMENTAL PROCEDURES

2.1 Wind Tunnel

The 5 cm wind tunnels that were used in the present investigations have been previously described, and are the same as those used for similar earlier studies on glass.⁶ In order to expose the agent to the wind flow, the piston was removed and the test substrate (a 1.5 in. diameter circle) with the droplet of agent on it was placed onto the piston and inserted into the wind tunnel. The humidified, temperature-controlled air from a Miller-Nelson Environmental Control Unit ([ECU] tunnel a) or an Aalborg MFC (tunnels c, d, k, and l) was then passed over the sample, and the vapors were collected on Markes Tenax® thermal desorption tubes at the vapor sampling inlet. The amount of agent on each tube was measured based upon a standard in the Gas Chromatography/Mass Spectrometry (GC/MS). The sample volume and tunnel air flow rate were known, thus the agent concentration (mg/m^3) and evaporation rate ($\mu\text{g/min}$) could be calculated. The rates were not calculated for the initial 5 min of the experiment, before the instrumentation had reached equilibrium, nor at the end of the experiment, when the concentration of mustard was nearing a plateau due to sample exhaustion. Hence, the data in the middle of each experimental run were used to calculate the evaporation rates.

Air flows were 18, 181, and 405 standard liters per minute (SLPM), which corresponded to velocity values at a 1 cm height of 0.22, 1.7 and 3.6 m/sec. The flow volume per thermal desorption tube was typically 2 to 10 L volume, and the tubes were automatically switched using a proprietary Versatile Tube Sampler. The rate at which the tubes were switched was adjusted based upon the evaporation rate of the agent. The air and substrate temperatures

investigated in this work were 15, 35, and 50 °C, and the droplet sizes were 1, 6, and 9 µL, corresponding to droplet diameters of 1.24, 2.25, and 2.58 mm and contamination densities of ~1.3, 7, and 11 g/m².

The droplet masses used in the calculations and tables were based upon the pipette setting; the samples were not weighed due to the small mass of agent compared to the much larger mass of the concrete.

2.2 Agent

Sulfur mustard, {bis(2-chloroethyl) sulfide, ClCH₂CH₂)₂S}, is commonly abbreviated H for munition-grade and HD for distilled agent. Distillation removes the impurities that are commonly present in munition-grade mustard, including Q (sesquimustard, bis(2-chloroethylthio) ethane, ClCH₂CH₂SCH₂CH₂SCH₂CH₂Cl, 10.1%) the cyclic ether 1,4-dithiane, (S(CH₂CH₂)₂S, 3.2%), 1,2-dichloroethane (2.6%) and 4-chlorobutyl 2-chloroethyl sulfide (1.0%), and 16 other analytes (totaling 3.9%). **Caution: sulfur mustard is a potent vesicant, and care must be taken to prevent exposure to liquid or vapor. It should only be manipulated by trained personnel employing appropriate engineering controls and personal protective equipment.**

2.3 GC with MS Detection

The protocol used in the present work was the same as that used for the studies of the evaporation of HD from glass and H from sand. GC/MS analysis of the thermal desorption tubes was performed using a Markes UNITY/ULTRA Thermal Desorption system connected to an Agilent Technologies 6890N GC/5973 MSD equipped with a 30 m x 0.25 mm HP-5 capillary column (Agilent Technologies, Wilmington, DE). The thermal desorption tubes used were Markes Tenax thermal desorption tubes (Markes International, Llantrisant, UK, Part #C0102S). Each sample was prepurged for 1 min and then desorbed for 2.5 min at 250 °C. The transfer line to the GC was heated to 180 °C. The GC oven temperature profile was ramped from 75 °C (2 min), to 110 °C at 20 °C/min, to 290 °C at 80 °C/min. The column flow rate (at 75 °C) was 1.6 mL/min (46 cm/sec) at a constant pressure of 15 psig. The temperatures were injection at 250 °C; MSD transfer line at 180 °C; MSD quadrupole at 150 °C; and MSD source at 230 °C. The sample extracts were analyzed in the electron impact (EI) mode scanning from 30-300 amu, with 2.78 scans/sec. Under these conditions, HD eluted at ~2 min (Figure 2). Both sulfur mustard and a breakdown ion were seen in the mass spectrum (Figure 3).

2.4 Substrates

The concrete (C04) was the same as that used in previous sulfur mustard degradation studies.^{7,8} The C04 concrete had the nominal formulation of 16.5% Portland cement, 34.2% natural river siliceous sand as fine aggregate, 49.3% Calcrea Alabama limestone coarse aggregate, which was ~1 cm in diameter (Figure 1), and a 0.45 water-to-cement ratio. The concrete was made in 2004 and was ~2 years old when used. Both nitrogen gas absorption and mercury intrusion porosimetry (MIP) were used to determine the pore diameter and volume

of small monoliths of concrete (Table 1, Appendices A, B, and C)*. The concrete samples submitted for measurement were chunks of ~0.5 mm diameter; the large aggregate was eliminated due to the size requirements of the instrumentation used. The pH of water in which the concrete was submerged for 24 h was 12 (0.2 g concrete in 2 mL water). The higher surface area and pore volume observed from the MIP experiments may be due to the pressure of the mercury breaking smaller pore walls within the concrete, and thus creating surface area as the experiment progressed. The top side of the concrete had been brushed before curing to give a rippled effect (Figure 2); the ripples were about 1 cm in wavelength. The bottom of the concrete was the side that had been in the mold; a mold release agent had been used. The bottom surface was porous with visible pores that were 1-2 mm in diameter and aggregate was seen on the bottom surface. Most of the samples were spiked on the bottom of the concrete; a few were spiked on the rippled top side and are annotated 'R' in the list of data in Appendix D. A few samples of concrete were artificially 'weathered' by abrasion against an outdoor piece of concrete on the rippled side; these are annotated 'RW' in the Tables.

Table 1. Physical Properties of C04 Concrete.

2.5

Experimental Design and Data Analysis

The experimental design was generated and the data were analyzed using JMP[®] Statistical Discovery Software. The three variables were temperature, drop size, and air flow rate at three levels each. Measuring all combinations of these levels would yield 27 conditions ($3 \times 3 \times 3$); the cubic composite design chosen required 9 conditions, which can be described as the vertices of a cube and the cube's center. The data were collected in triplicate as two blocks of four vertices (chosen as the corners of a tetrahedron) and the mid-point. This collection of

data allowed for the determination of the major contributing variables and interactions among variables. The substrate temperature (°C), droplet mass (mg), air flow (SLPM), total percent sulfur mustard recovered, and tunnel identity (three similar 5 cm tunnels, named a, c, and d, were available) were treated as variables that may affect the raw evaporation rate. Effect interactions among droplet mass, air flow, and temperature were included in the numerical analysis.

3. RESULTS AND DISCUSSION

3.1 Munition-grade H on Concrete

Sixty-one experiments were performed and two low-temperature datasets were removed as outliers based on the statistical analyses (original wind tunnel vapor concentrations are shown in Appendix E). Least squares regression analyses were performed with the 44 experiments that were munition-grade on the molded side of the C04, and the formulae were applied to the rippled surfaces with H and the molded side with HD to compare the fit of the data (Appendix D). Relative humidity (RH) was not tested as a factor because of the paucity of the data and the recent results that suggest that RH has little or no influence on HD volatility.⁹ The identity of the tunnel had no discernable effect on the evaporation rate.

The average vapor recovery of the agent was 53% and the 95% confidence range was 47 to 60% (Figure 4a, Table 2). By comparison, the vapor recovery was 75% from sand and 86% from glass using the vapor method. Photographs showed that the evaporation from glass was 100%. Thus, the 53% recovery of agent from concrete and sand may be corrected to 67%. Because sulfur mustard was left in the concrete, the reactivity, degradation, and transport in the concrete must be studied in order to determine the final fate of the sulfur mustard.

Prior analyses of the evaporation data of HD on glass showed that normalization of each evaporation curve to 100% provided a set of consistent rates.¹⁰ Analysis of the HD on glass data using normalized evaporation rates or the raw evaporation rate plus the fractional vapor recovery yielded the same result. Thus, the same method was used to analyze the concrete data.

The evaporation rate of the sulfur mustard increased while spreading over the surface of the concrete, then decreased quickly as the surface contamination was exhausted, and the balance of the agent was trapped in the concrete (Figure 5). The evaporation rate was calculated from the decreasing sulfur mustard concentrations after the agent had spread, which corresponded to about 0.25 h in Figure 5.

The variation of evaporation rate with temperature, drop size, and wind speed is shown in the cubic plot in Figure 6. The bulk of the experiments were performed on the molded surface. The experiments performed on the rippled surface are written in brackets and tagged (R). The average evaporation rates from the rippled surface are lower than those from the molded surface. The distributions of the raw evaporation rate and $\log_{10}(\text{evaporation rate})$ (Figures 4b and 4c, Table 2) are based on the 44 experiments on the molded surface (Table E1).

A least squares regression analysis method was used to fit the evaporation rates from the molded surface to the variables of drop size, wind speed, and air flow; $r^2 = 0.77$; $r^2_{adj} = 0.72$, $n = 44$ (Figure 7, Tables 3 and 4). The \log_{10} (evaporation rate) was similarly calculated and predicted, with $r^2 = 0.74$; $r^2_{adj} = 0.68$, $n = 44$ (Figure 8, Tables 3 and 4). Unlike the analyses of the glass and sand data, the r^2 was higher for the raw evaporation rates than for the \log_{10} (evaporation rate). The negative intercept for the regression line may reflect the fact that the evaporation rates were low at 15 °C, which was close to the freezing point of sulfur mustard (14.5 °C).

Raw Evaporation Rate =

$$\begin{aligned} & -108 + (2.2 * \text{temp}) + (6.1 * \text{H mass only}) + (0.11 * \text{SLPM}) \\ & + 0.19(\text{temp}-35.4)(\text{H mass only}-5.6) + 0.005(\text{temp}-35.4)(\text{SLPM}-177.9) \end{aligned} \quad (1)$$

$\log_{10}(\text{Raw Evaporation Rate}) =$

$$\begin{aligned} & (0.02 * \text{temp}) + (0.06 * \text{H mass only}) + (0.0008 * \%RH) \\ & + (0.006 * \% \text{vapor recovered}) \end{aligned} \quad (2)$$

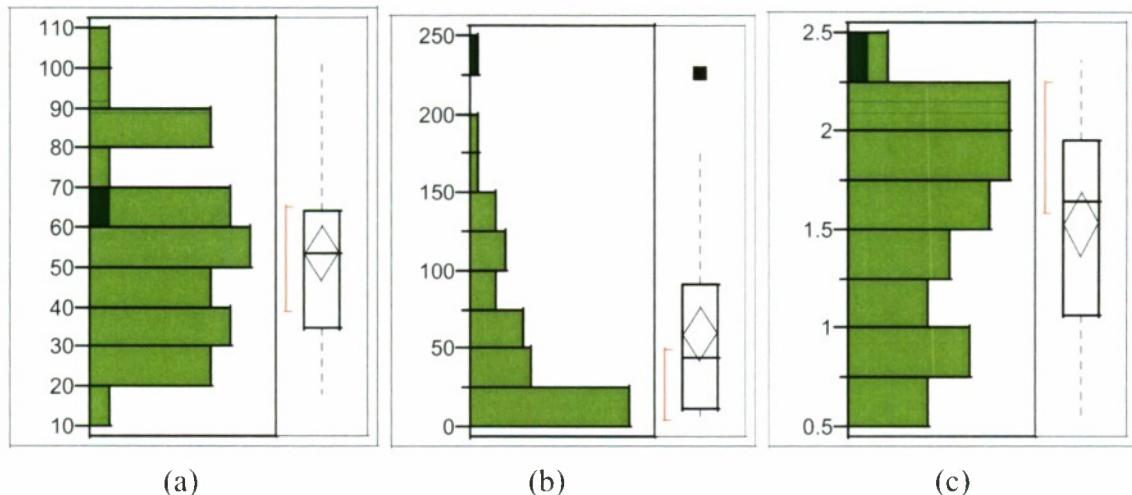

Figure 4. Distributions of (a) %Vapor Recovered, (b) Raw Evaporation Rate, and (c) \log_{10} (Raw Evaporation Rate). The dark boxes in the distributions correspond to the highest evaporation rate sample; the rectangles correspond to the 25th and 75th quartiles; the line in the rectangles corresponds to the mean; and the diamonds correspond to the 95% confidence interval.

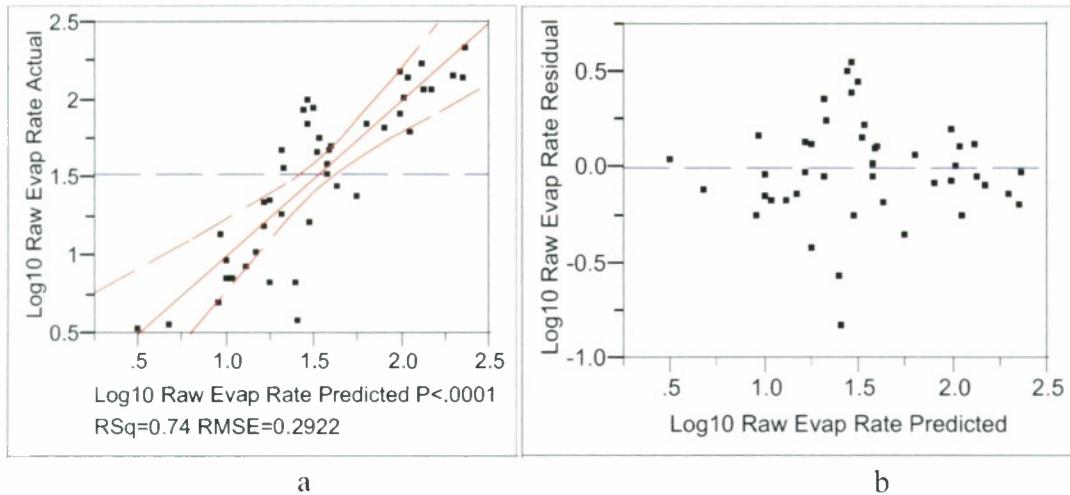

Figure 8. Plot of (a) Actual vs. Predicted Values (dashed lines are the 95% confidence intervals) and (b) Residuals for $\text{Log}_{10}(\text{Raw Evaporation rate})$ ($\mu\text{g}/\text{min}$) of Sulfur Mustard from C04 Concrete.

Once the regression curves for the 44 experiments of munition-grade sulfur mustard had been calculated, the curves were used to predict the evaporation rates of the munition grade sulfur mustard on the rippled surface and CASARM grade sulfur mustard on the molded surface. The predictions thus obtained are shown in Figures 9 and 10. The evaporation rates from the rippled surfaces using CASARM grade sulfur mustard (HD) fell within the envelope of predictions based on the 44 experiments, suggesting that the identity of the sulfur mustard and the morphology of the surfaces were not major contributors to the evaporation rate.

In addition, an ANOVA method was used to compare the raw evaporation rates of the agent on the different concrete surfaces and to compare the H versus HD.¹¹ None of the variations in substrate or agent made a statistically significant difference (Figure 11, Table 5).

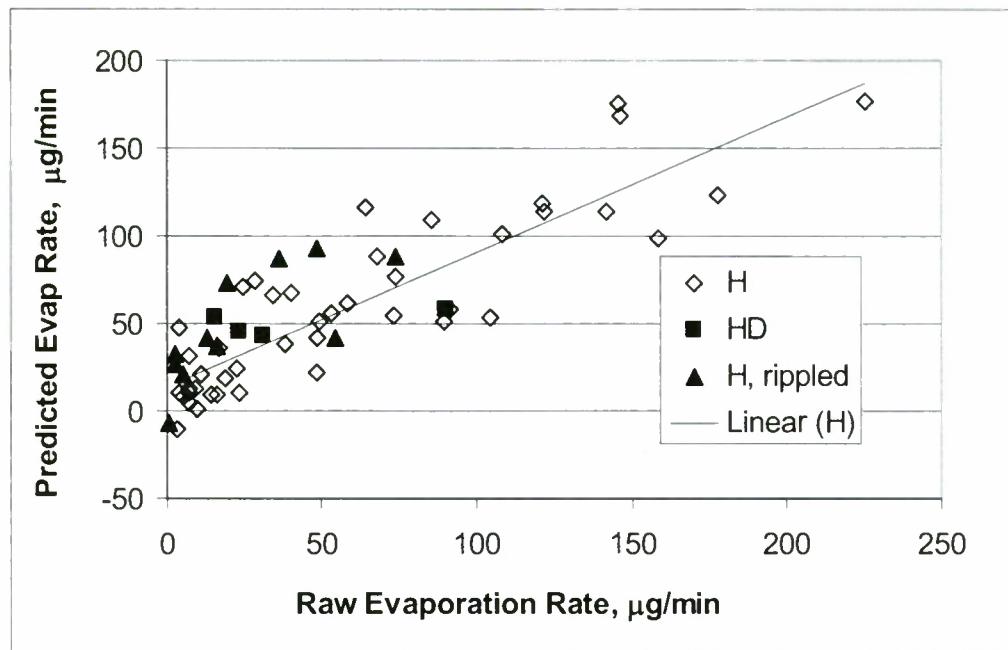

Figure 9. Evaporation of H from Concrete: Comparison of HD on Bottom (■) and H on Rippled Top Surface (▲) to H on Bottom (◇).

	NM	HD	4	40.0500	16.462	4.181	75.919

[†] Std Error used a pooled estimate of error variance.

[‡] One ANOVA was performed to compare NM to R, another compared H with HD.

3.2

Comparison of Glass, Sand, and Concrete

Evaporation profiles of sulfur mustard from glass, sand, and concrete at the same environmental conditions are shown in Figure 12. The evaporation profile on concrete was different from the sand and glass. The rate began higher and increased slowly as the H spread over the surface of the concrete, then decreased quickly as the surface H was exhausted, and the balance of the agent was trapped in the pores of the concrete. By contrast, previous work showed that the evaporation of CASARM sulfur mustard from glass occurred from a sessile droplet with a constant base and the contact angle changing during the evaporation.¹² Previous studies also showed that sulfur mustard absorbed into sand within 0.1 sec¹³ although evaporation from the surface occurred for several hours (Figure 12).

The evaporation rates on the three substrates at different conditions are shown in a cube plot (Figure 13). On all three substrates, the evaporation rate increased with drop mass, temperature, and wind speed. Concrete had the highest evaporation rate in all cases except the high temperature-large drop size-high air flow condition (Figure 13).

The equations that resulted for the evaporation rate and $\log_{10}(\text{evaporation rate})$ of HD from glass¹ were applied to the munition sulfur mustard from UK sand² and concrete wind tunnel measurements (Figures 14 and 15). This comparison was done using the actual mass of sulfur mustard, which corrected the 97% purity of CASARM HD and 77% purity of munition H.

The raw evaporation rates from glass and sand gave straight lines ($r^2 = 0.86$ and 0.87, respectively); the concrete data had a large degree of scatter ($r^2 = 0.69$). The raw evaporation rates trended higher for the concrete than for the glass and sands. Interestingly, although likely coincidentally, the raw evaporation rate regression lines for the glass and concrete were roughly parallel with an offset. The regression lines for the glass roughly followed the diagonal of the graph, as expected.

Applying the $\log_{10}(\text{evaporation rate})$ derived from glass to glass and sand gave straight lines ($r^2 = 0.91$ and 0.93, respectively). Although the data were clustered, the concrete data showed more scatter ($r^2 = 0.58$) than the glass and sand data.

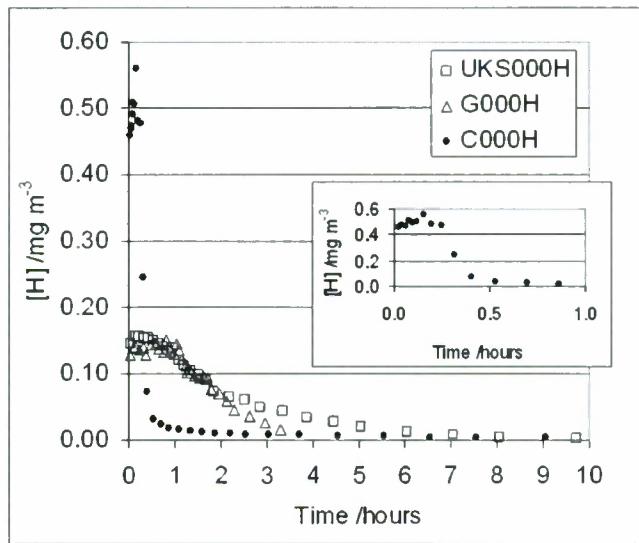

Figure 12. Plot of Vapor Concentration vs. Time for Evaporation of Munition-grade Sulfur Mustard (H) from Glass (\triangle), Sand (\square), and Concrete (\bullet) at 35 °C, 6 μL Drop, 181 SLPM Air Flow. Inset shows evaporation rate profile from concrete in more detail.

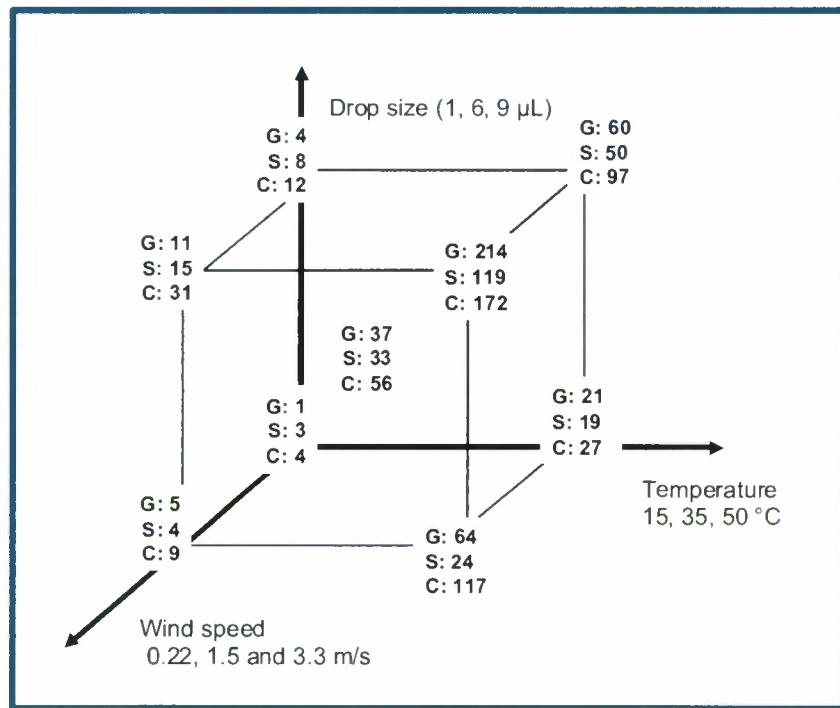

Figure 13. Cube Plot Showing Average Evaporation Rates ($\mu\text{g}/\text{min}$) of HD from Glass (G), and H from Sand (S) and Concrete (C).

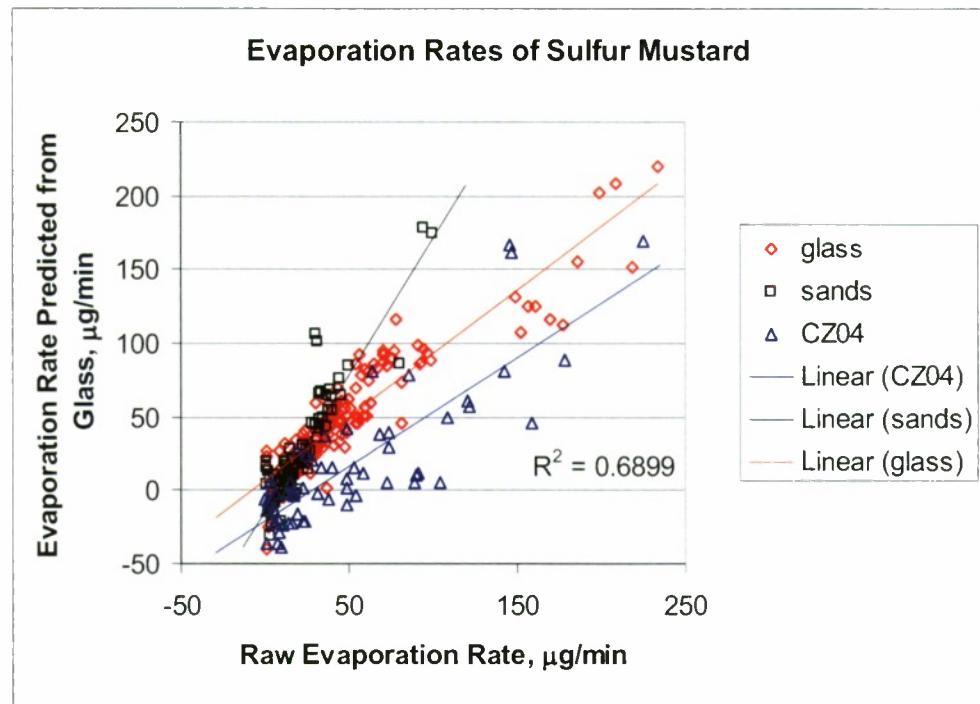

Figure 14. Prediction of Evaporation Rates of Sulfur Mustard: HD from Glass (\diamond), H from Sands (\square), and H from Concrete (Δ) Using Equation Derived for Glass.

3.3

Recommendations for Future Projects

The following recommendations were determined for future projects:

- Gauge the effect of variations in porous substrates from diverse sources by measuring agent evaporation rates and the percentage agent evaporated at one condition.
- Measure the agent vapor concentrations after rain events.
- Determine the long-term scenarios in which the entrained agent will be mobilized from or transported within the porous substrate after the secondary evaporation event.
- Thoroughly analyze all prior agent evaporation studies and models, and compare data to models to indicate where gaps in the experimental data reside.

4.

CONCLUSIONS

The evaporation rate of HD from glass and H from sand and concrete rose with increasing temperature, drop size, and wind speed. The evaporation rates for the concrete exhibited a greater degree of scatter than the rates from glass and sand, likely due to the variability in the morphology of the concrete. The generic response of the evaporation rate to the environmental conditions was common to all three substrates although the magnitude of the response, the evaporation profiles, and the mechanisms of evaporation (from a sessile droplet on glass, from a subsurface pool of agent on sand, and from a droplet that spread on the surface and then adsorbed on concrete) differed. The percentage of agent that remained in the substrate also differed – 0%, 89% and 67% on glass, sand, and concrete, respectively.

Surface Area Reports

ASAP 2420 V2.02 J

Unit 2 Port 4

Serial #: 106

Page 15

Sample: CZ2004 Q3
Operator: AT
Submitter: SAIC
File: C:\2420\2007\10OCT\07-4316.SMP

Started: 10/26/2007 3:36:45PM
Completed: 10/27/2007 2:12:52AM
Report Time: 10/30/2007 9:27:00AM
Sample Mass: 0.5100 g
Cold Free Space: 86.7000 cm³
Low Pressure Dose: 0.200 cm³/g STP

Analysis Adsorptive: N2
Analysis Bath Temp.: 77.300 K
Thermal Correction: No
Warm Free Space: 28.2500 cm³ Entered
Equilibration Interval: 20 s
Automatic Degas: No

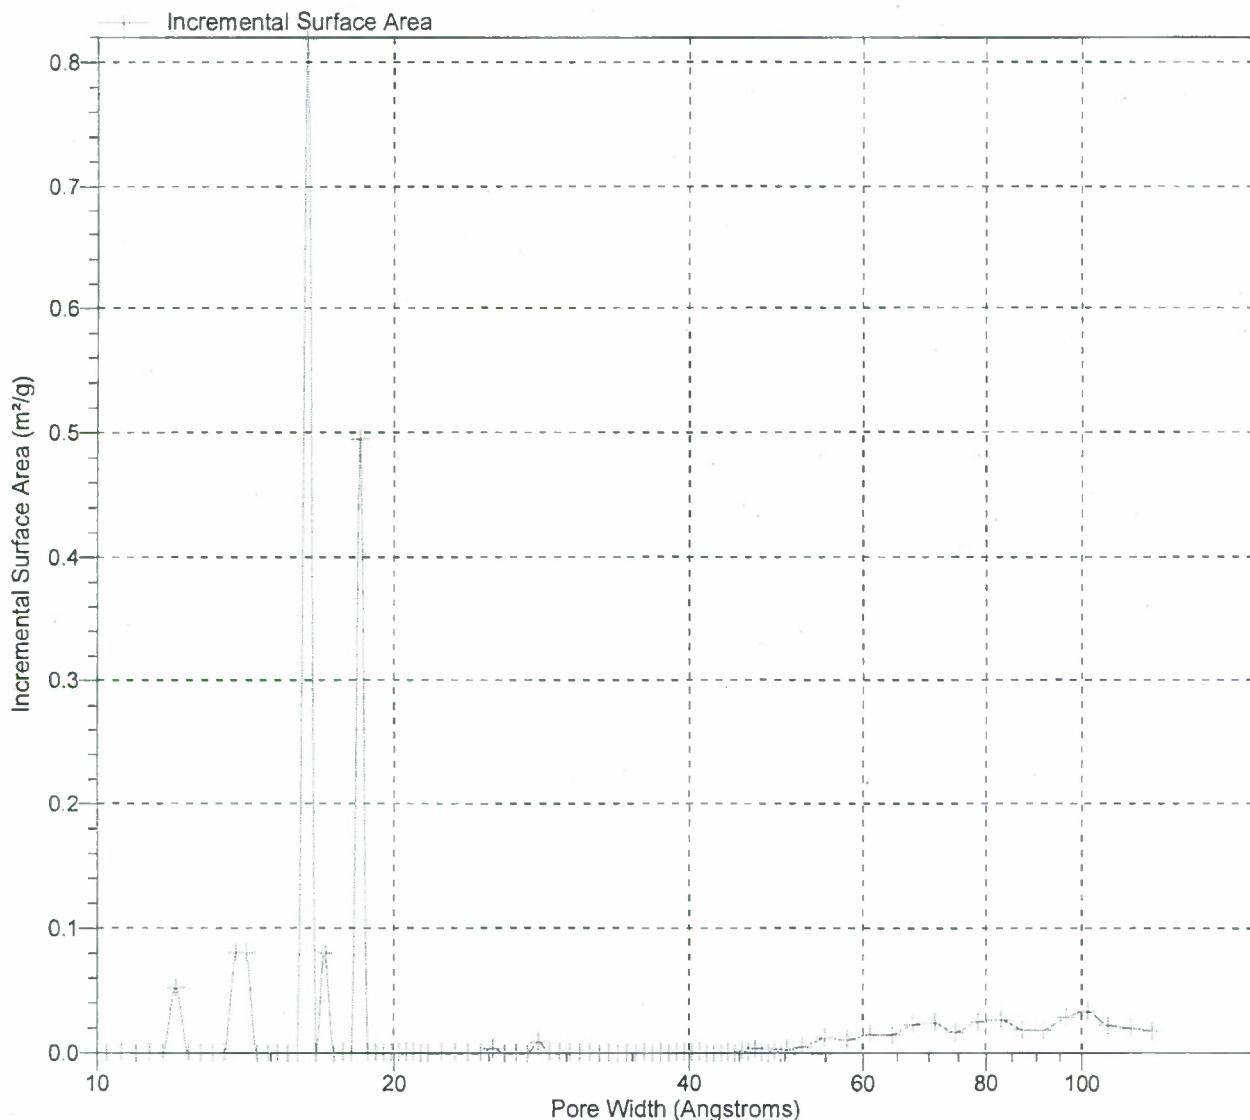

Cumulative Surface Area vs. Pore Width

Sample: CZ2004 Q3
Operator: AT
Submitter: SAIC
File: C:\2420\2007\10OCT\07-4316.SMP

Summary Report**Penetrometer parameters**

Penetrometer:	200 - (07) 5 Bulb, 0.392 Stem, Solid		
Pen. Constant:	10.790 μ L/pF	Pen. Weight:	56.5304 g
Stem Volume:	0.3920 mL	Max. Head Pressure:	4.4500 psia
Pen. Volume:	6.0041 mL	Assembly Weight:	127.8532 g

Hg Parameters

Adv. Contact Angle:	130.000 degrees	Rec. Contact Angle:	130.000 degrees
Hg Surface Tension:	485.000 dynes/cm	Hg Density:	13.5335 g/mL

Low Pressure:

Evacuation Pressure:	50 μ mHg
Evacuation Time:	5 mins
Mercury Filling Pressure:	0.51 psia
Equilibration Time:	10 secs

High Pressure:

Equilibration Time:	10 secs
---------------------	---------

No Blank Correction

Intrusion Data Summary

Total Intrusion Volume =	0.0574 mL/g
Total Pore Area =	10.364 m^2/g
Median Pore Diameter (Volume) =	0.0895 μ m
Median Pore Diameter (Area) =	0.0050 μ m
Average Pore Diameter (4V/A) =	0.0222 μ m
Bulk Density at 0.51 psia =	2.2180 g/mL
Apparent (skeletal) Density =	2.5417 g/mL
Porosity =	12.7387 %
Stem Volume Used =	29 %

File: C:\...\04APRIL\05-0860.SMP

Started: 4/20/2005 4:08:31PM Analysis Adsorptive: N2
Completed: 4/21/2005 4:54:10AM Analysis Bath Temp.: 77.300 K
Report Time: 4/21/2005 7:33:54AM Sample Mass: 3.9107 g
Warm Free Space: 7.6235 cm³ Measured Cold Free Space: 21.4787 cm³ Measured
Equilibration Interval: 15 s Low Pressure Dose: None
Sample Density: 1.000 g/cm³ Automatic Degas: Yes

Sample Prep: Stage	Soak Temperature (°C)	Ramp Rate (°C/min)	Soak Time (min)
1	110	10	960

Summary Report

Surface Area

Single point surface area at P/Po = 0.290614370: 2.9687 m²/g

BET Surface Area: 3.0351 m²/g

t-Plot Micropore Area: 0.2953 m²/g

t-Plot External Surface Area: 2.7399 m²/g

BJH Adsorption cumulative surface area of pores
between 17.000 Å and 3000.000 Å diameter: 3.2382 m²/g

Pore Volume

Single point adsorption total pore volume of pores
less than 2556.829 Å diameter at P/Po = 0.992391303: 0.022531 cm³/g

Single point desorption total pore volume of pores
less than 3895.491 Å diameter at P/Po = 0.995029096: 0.026921 cm³/g

t-Plot micropore volume: 0.000137 cm³/g

BJH Adsorption cumulative volume of pores
between 17.000 Å and 3000.000 Å diameter: 0.018371 cm³/g

Pore Size

Adsorption average pore width (4V/A by BET): 296.9365 Å

Desorption average pore width (4V/A by BET): 354.7930 Å

BJH Adsorption average pore diameter (4V/A): 226.925 Å

<p>The graph plots Agent Remaining (%) on the left y-axis (0% to 120%) and Agent in mg/m³ on the right y-axis (0.00 to 5.00) against Time in minutes (0 to 2500). Two data series are shown: Thermal Tubes (represented by diamonds) and Agent in mg/m³ (represented by triangles). Both series show a sharp initial drop from 100% to approximately 40% remaining agent within the first 500 minutes. After this initial drop, the agent levels remain relatively stable around 40% remaining agent until about 1500 minutes, after which they begin to rise again towards 100% remaining agent by 2500 minutes.</p>
